INTRODUCTION

This codebook provides documentation of the contents of 12,149 data records for the 2002 Department of Defense Survey of Health Related Behaviors Among Military Personnel. Five files and an electronic version of this codebook are provided on one CD-ROM:

- PUF02.DBS: an ASCII data file
- PUF02.SAS7BDAT: a SAS data file
- PUF02.SAV: an SPSS data file without formatting
- VARFORMATS.TXT: an ASCII file containing format information
- CONVERT.SAS: a SAS program to convert ASCII data into SAS data
- PUF02.DOC: a Microsoft Word codebook document

Codebook Layout

Documentation includes descriptions of sampling variables, questionnaire items, and composite variables and indexes. For each variable, the following is provided:

- LABEL: variable name
- A/N: indication of whether the variable is alphabetic (A) or numeric (N)
- LEN: variable length (the number of columns for the variable in the ASCII file)
- BEG: beginning column position of the variable in the ASCII file
- END: ending column position of the variable in the ASCII file
- DESCRIPTION: operational definition of the variable (DESCRIPTION is limited to 50 characters; therefore, for many variables, words are abbreviated to encompass the entire operational definition)

For variables with discrete categories, all possible response categories are listed under each variable description. Exceptions to this convention are described in the next section. In addition to the coded value of the response category (e.g., 1 = yes, 2 = no), the frequency of responses within each category (e.g., 100 people answered “yes”) is included. For all continuous variables, the range of responses is provided along with an interpretation of the meaning of any value falling within that range.

For both discrete and continuous variables, categories termed “consistency codes” also are listed and their respective frequencies included. Values and consistency codes that did not get assigned for a given variable are indicated by frequencies of zero. The consistency codes included for each variable are as follows:

- -3 = not applicable
- -5 = bad data, logically assigned
- -6 = multiple response
- -8 = blank (no answer)
- -9 = legitimate skip

These assigned codes define all possible missing data values consistently for each variable. Details about the meaning of these codes and how they were assigned are discussed later in this introduction.

Types of Variables

Five types of variables are described in this codebook:

- unedited, or “raw,” variables
- variables that have been edited for consistency with other responses within a record (i.e., “edited” variables)
- variables that have been edited for consistency against other variables (i.e., “recoded” variables)
- variables that have been both edited for consistency with other variables and have undergone a statistical imputation procedure to replace any remaining missing data with nonmissing values (i.e., “imputed” variables)
- new variables that were created (directly or indirectly) from the questionnaire variables for purposes of analysis (i.e., “created” variables)

Unedited, or “raw,” variables have undergone no editing for consistency with other responses in a record, other than assignment of some standard consistency codes for multiple marks and questions that were not answered (see below). These variables are denoted with a “Q,” followed by the question number (e.g., Q6). Because these variables have not been edited for consistency with any of the respondent’s other answers, some inconsistencies may be present between these raw variables and other variables in a record.

Variables for which responses may have been edited for consistency with other responses within a record are denoted by the prefix “ED.” For example, EDQ45 is a question about most recent use of cigarettes. If a respondent did not answer or indicated that he/she last smoked more than 30 days ago, but the response to Question 46 indicated that the person must have smoked in the past 30 days, EDQ45 was given a “logically assigned” value to indicate that the respondent last smoked in the past 30 days. For these edited variables, the coding indicates where values have been logically assigned for consistency with the values in other variables.

Variables for which responses have been edited for consistency against other variables are denoted by the prefix “R.” For example, RQ126_1 through RQ126_11 are subitems within Question 126 concerning reasons for inability to deploy. Respondents were instructed to mark all reasons for their inability to deploy during the past 12 months. When scanned, each individual subitem within this question is scored independently such that an unmarked box is coded as a “0” and a marked box is coded as a “1.” Because all other items with dichotomous, mutually exclusive response options (such as EDQ140) are coded such that 1 = “yes” and 2 = “no,” all of the RQ126 subitems with unchecked boxes were recoded from a “0” to a “2.”

For some key sampling and demographic variables, logical editing was done as much as possible to replace missing values with nonmissing values based on other available information in the questionnaire. For example, records with missing data on pay grade (i.e., Question 2) were compared with values for education and age (Questions 3 and 4), which are related to pay grade, in order to assign nonmissing values to the pay grade variable.

Following logical editing of key sampling and demographic variables, any additional missing data were replaced with nonmissing values using the statistical procedure of “hot-deck” imputation. In the hot-deck procedure, records were first sorted by Service and then were progressively sorted on demographic characteristics, such as age and education. This sorting produced an ordered data file in which adjacent data records represent individuals with similar characteristics. A missing value for each particular variable then was replaced by the nonmissing response for the same variable in the last encountered record in the sorted data base. Variables for which any remaining missing data have been statistically imputed with nonmissing values are denoted by the prefix “IR” (e.g., IRQ4), to denote that these are “imputation-revised” variables.

For some of the analyses conducted for the 2002 final report, new variables were created from the raw, edited, or imputed variables in the questionnaire, also known as the “source” variables. For example, the variable OVWGT is an indicator of whether a respondent was

classified as overweight according to the Body Mass Index (BMI), which is defined as the ratio of a person's weight (in kilograms) to the square of the person's height (in meters). Because the questionnaire asked respondents for their weight in pounds and their height in feet and inches, these source variables were converted to the appropriate metric system values. The BMI then was calculated, and the resulting values were compared with age- and gender-specific cut points to classify a respondent as overweight or not overweight.

Consistency Codes

As discussed earlier, consistency codes indicating all possible missing data values are indicated, along with their respective frequencies, for each variable in the codebook. In general, the interpretation of these codes is straightforward. In particular, the following codes could be assigned prior to any editing of the variables:

- -6 = multiple response (i.e., more than one bubble darkened)
- -8 = blank (no answer)

New variables that were created based on one or more “source” variables from the questionnaire also were assigned values of -8 if the source variables did not contain sufficient information to assign a value to the created variable.

The following missing values could have been logically assigned after variables had been edited for consistency with other variables in the record:

- -5 = bad data
- -9 = legitimate skip

In the editing stage, the “bad data” value was usually assigned in one of two situations:

(a) the respondent gave an answer that was inconsistent with answers to other questions, or (b) the respondent gave an out-of-range answer. For example, an age in Question 43 (i.e., age when respondent first started smoking regularly) that was greater than the final value for the respondent's age was treated as inconsistent with the respondent's age. In addition, some raw continuous variables that required respondents to enter their answers in a grid (e.g., Q40, for age at first use of alcohol) were assigned a code of -5 (i.e., “bad data”) if respondents entered a number in the “tens” column but left the “units” column blank. For example, if a respondent entered a “1” in the “tens” column of Q40 but left the “units” column blank, a strict interpretation of this pattern was that the respondent's age at first use could be any number from 10 to 19. Furthermore, respondents were instructed to complete grids by starting with the righthand box (i.e., the “units” box) and working

leftward. Therefore, the “bad data” code signifies in this situation that (a) respondents did not follow instructions correctly in completing the grid, and (b) it was not possible to infer a value from the data that were provided.

A “legitimate skip” value was assigned when a question was left blank because of some instruction in the questionnaire, and the blank was consistent with other data in the record. For example, male respondents were instructed to stop once they completed Question 138 and not complete the remaining questions about women’s health (Questions 139–142). Blank values in Questions 139 through 142 were assigned values of –9 if the respondent was male. Thus, the “legitimate skip” (–9) and “blank (no answer)” (–8) values allow users of the data to distinguish between situations where a question was left blank when something should have been answered (i.e., –8) and situations where a question was left blank because the respondent was supposed to leave it blank (i.e., –9).

For some *created* analysis variables, the following consistency code also was added in special circumstances:

- –3 = not applicable

The “not applicable” code was sometimes assigned to created analysis variables to exclude cases from both the denominator and the numerator in the subsequent analyses. For example, “not applicable” codes were assigned to women’s health analysis variables, such as ALCPREG (i.e., alcohol use during most recent pregnancy), if the respondent was male or, for female respondents, if they had never been pregnant or their last pregnancies were more than 5 years ago.

Data Privacy and Statistical Disclosure Limitation

With the enactment of new regulations in European Union countries and the United States, data producers have become increasingly aware of the importance of protecting respondent confidentiality. At the same time, data producers are faced with a critical problem inherent in most confidentiality treatment schemes: a resulting loss of valuable analytic utility. Key to solving this problem is an innovative probabilistic framework for measuring, and then controlling, both disclosure risk and information loss. RTI’s MASSCSM technology offers such a framework, using the theory of survey sampling to provide “disclosure-safe” databases. This Public Use File was created using MASSC technology for limiting statistical disclosure.

Advantages of MASSC

All nonsynthetic methods, including MASSC, use some form of perturbation (e.g., recoding, swapping, or noise addition) and suppression (e.g., suppressing a field or the whole record). The main concerns surrounding non-MASSC methods include the following:

- inability to measure risk and information loss
- possibility of too much bias due to the treatment of all records found to be potentially at risk
- lack of standard software for analysis of treated data
- lack of protection against intruder's knowledge about new identifying variables
- no protection for nonunique records with common values for a sensitive variable
- internal inconsistency among separately treated subsets of tabular data

MASSC overcomes these concerns by working at the micro level and submitting all records for possible treatment, while only a small, randomly selected subset is actually treated. By relying partly on random perturbation and partly on random suppression, MASSC limits the introduction of bias and variance. With this stochastic framework, MASSC introduces sufficient uncertainty about the presence and identity of a target, enabling the use of sensitive databases not previously available to analysts due to confidentiality concerns. Applicable to categorical and continuous data, as well as linked data, MASSC provides an important statistical alternative when releasing data containing sensitive information.

MASSC offers several major benefits:

- measuring disclosure risk and information loss without modeling assumptions
- controlling for both disclosure risk and information loss
- offering a unified approach to both tabular and micro data
- allowing use of standard tools to analyze MASSC-treated data sets

How It Works

MASSC embodies a statistical method for disclosure limitation comprising four steps:

- **Micro Agglomeration** creates risk strata and checks for records at risk. This step controls the number of records initially at risk by determining the fineness of the categories of identifying variables to be released.

- Substitution uses optimal sampling rates to select records at random for perturbation, subject to substitution bias constraints. This step introduces uncertainty about the identity of a target.
- Subsampling uses optimal sampling rates to select, at random, records from the substituted database for suppression, subject to precision constraints. This step introduces uncertainty about the presence of a target.
- Calibration uses optimal weight calibration to adjust subsampling weights, subject to preserving key estimates from the original database. This step reduces bias due to substitution and reduces variance due to subsampling.

In applying MASSC to the DoD survey data, we introduced distortion via substitution and subsampling, and then made adjustments via calibration. First, the risk strata were created in the micro agglomeration step to calculate the proportion of records that had a unique combination of values for various identifying variables (IVs), such as age, race, and marital status, called “uniques.” If there were too many uniques, then further recoding of IVs into broader categories was performed to reduce their number. Thus, several variables with discrete response categories (e.g., EDQ11) were collapsed to reduce the risk of identity disclosure. A limited number of summary variables was also created and substituted for original variables. For example, EDQ6 and EDQ7 were replaced with FAMILY, and one variable, Q132, was eliminated from the data set to further reduce the risk of identity disclosure. It should be noted that the replacement of the continuous age variable with the categorical age variable precludes replication of the adjusted estimates as conducted in some tables within the 2002 final report.

Next, for each record, a substitution partner was assigned such that a suitable distance (Rao’s Quadratic Entropy, in particular) based on IVs between the recipient and the donor record was minimized. Risk strata were then subdivided into substrata such that each substratum had a relatively low contribution to bias due to substitution for a given set of selected study variables, such as drug use and heavy alcohol use, for various demographic domains. Next, using nonlinear optimization techniques, selection probabilities for substitution were obtained such that a disclosure cost function was minimized subject to a set of constraints on bias relative to the original estimate. For the PUF from the 2002 DoD survey, the substitution rates for individual substrata could vary depending on over/under treatment needed under optimization. When a record was selected for substitution, all variables related to the IVs were also substituted from the donor to maintain internal consistency.

Similarly, for the subsampling step of MASSC, risk strata were subdivided into substrata such that each stratum had a relatively low contribution to variance for a given set of study

variables. Then, using nonlinear optimization, selection probabilities for subsampling were determined such that a disclosure cost function was minimized subject to a set of constraints on sampling variance relative to the squared original estimate. For the 2002 DoD survey data, the subsampling rates for individual substrata could vary depending on over/under treatment as needed.

Based on unique and nonunique occurrence, substitution, and subsampling rates obtained from the above steps of MASSC, it was possible to compute measures of risk as part of the confidentiality diagnostics and check for their adequacy. For example, for a record appearing unique, the chance that it survived (was not substituted or sampled out) and was at risk of disclosure from an inside intruder (someone who knows an individual's responses are in the database) was about 12 percent for the 2002 DoD survey PUF. Similarly, for a record appearing nonunique double (i.e., one of a pair of records with the same IV values), the chance that it survived treatment and was at risk of disclosure was about 10 percent. For a record appearing nonunique triple, the risk was about 7 percent, and for a record appearing nonunique other (i.e., 4+), the risk was about 20 percent. This was deemed reasonably safe in analogy with tabular data, where a minimum cell size of 3 to 5 is often considered safe. This measure is quite conservative, because it is based on the assumption that the inside intruder knows several values for IVs. In addition to checking the adequacy of these quantitative measures, no variable was included in the PUF that provided more detailed information than the IVs considered in the treatment. Also the STRATUM and PSU identifiers were scrambled because they related to the geographic location of the respondent.

Finally, the last step of calibration in MASSC was applied to the substituted and subsampled data by adjusting the subsampling weights so that demographic subpopulation counts for domains defined by age, gender, and race-ethnicity were preserved in the treated data.

Before the PUF was released, several diagnostics for analytical quality were performed to determine the impact of disclosure treatment on bias and precision of estimates compared to the original estimates. In particular, for 364 study variables, point estimates and standard errors were computed before and after the treatment. The difference in point estimates was typically 0.1 percent, whereas the decrease in precision was less than 2 percent on average. The bias and variance constraints in MASSC in terms of point estimates for various domains provided basic quality protection for key study variables.

Although the MASSC process attempts to control the impact on bias and precision while minimizing disclosure risk, it is not possible to guarantee that inference for certain parameters will not change from the original database due to the random nature of perturbation and suppression

used in the treatment. For example, as can be seen in the shaded area of the table below, even though PUF and original estimates are very close, there may be a change of significance level. For example, in Table 3.1 in the final report, the untreated estimates for substance use measures in the analytic file for 2002 were as follows:

	Analytic File		PUF	
	Percent	S.D.	Percent	S.D.
Alcohol Drinking Levels				
Abstainer	23.0	(0.7)	23.1	(0.7)
Infrequent/light	18.3	(0.5)	18.3	(0.5)
Moderate	17.9	(0.5)	17.8	(0.5)
Moderate/heavy	22.7	(0.4)	22.8	(0.4)
Heavy	18.1	(1.1) ^a	18.0	(1.1)
Any Illicit Drug Use				
Past 30 days	3.4	(0.4)	3.4	(0.3)
Past 12 months	6.9	(0.7)	6.9	(0.6)
Cigarette Use, Past 30 Days				
Any smoking	33.8	(1.3) ^a	33.8	(1.3) ^a
Heavy smoking	13.1	(0.6)	13.0	(0.6)
Alcohol Use Negative Effects, Past 12 Months				
Serious consequences	9.6	(0.8) ^a	9.6	(0.8) ^a
Productivity loss	17.3	(0.9) ^a	17.2	(0.8) ^a
Dependence symptoms	12.3	(0.9) ^a	12.2	(0.9) ^a

^aComparisons between this survey and the 1998 survey are statistically significant at the 95% confidence level.

The estimates created using the MASSC are also shown in the table above. Note that there is a difference in significance levels between the 1998 and 2002 estimates of heavy alcohol use based on the analytic file and based on the PUF, even though the estimates of heavy use are highly similar for the two files. Specifically, the original estimate of 18.1 percent from the full analytic file was significantly different from the 1998 estimate of 15.4 percent, but using the PUF, the estimate of 18.0 percent was not significantly different from the 1998 estimate. Further examination indicated that this occurred because both estimates were very close to the criterion for meeting statistical significance at the 0.05 level. With the analytic file, the estimate was above the criterion; with the PUF, it was not.

Questions about the different data files, the contents of the records, or the associated documentation may be directed to the project director for the survey:
